Definition

In contrast to a conventional programming language which are (typically) used to describe software, a **Hardware Description Language (HDL)** is used to describe (or model) hardware (e.g., digital logic).

► (Selected) examples:

1. **Verilog**
2. **VHDL**
3. **MyHDL** ⊂ **Python**
4. **Chisel** ⊂ **Scala**
- ⋮

► Agenda: Verilog, or, more specifically,

1. foundational concepts,
2. low-level modelling,
3. high-level modelling, and
4. development concepts, e.g., testing and test stimuli.

► Caveat!

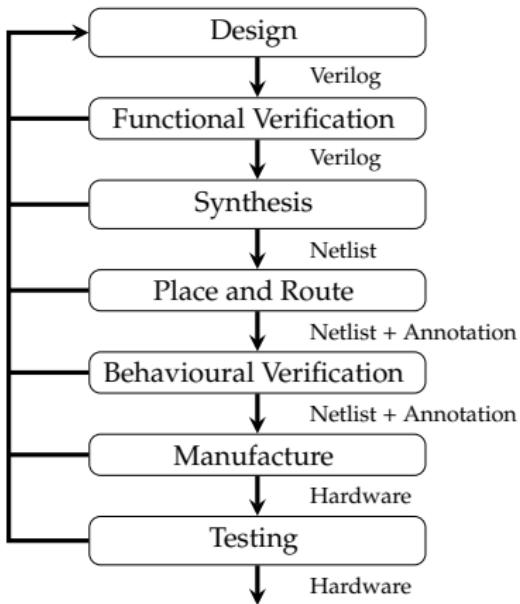

~ 2.5 hours ⇒ introductory coverage of *core* language features and workflow.

Part 1: foundational concepts (1)

- ▶ **Question:** *why?*!
- ▶ **Answer:** HDLs (and EDA tools more generally) help to
 1. facilitate automation, e.g., with respect to
 - ▶ simulation,
 - ▶ verification, and
 - ▶ translationof what is a more clearly machine-readable design,
 2. address the challenge of scale, e.g., with respect to design size and complexity.

Part 1: foundational concepts (2)

- ▶ **Question:** *how?!*
- ▶ **Answer:** as part of a broader development workflow, such as

- ▶ You can think of

synthesis \simeq compilation
place and route \simeq linking

since

- ▶ the former translates from high- to low-level, in this case a HDL model to a gate-level netlist,
- ▶ the latter works out how to use the standard cell library (e.g., the type and location of gates).
- ▶ Verification steps rely on simulation of the model at different levels of detail.

Part 1: foundational concepts (3)

► Analogy:

C

- ▶ A **program** is described using static **function definitions**.
- ▶ Each **function** has an interface (i.e., what it does and how it can be used) and a body (i.e., how it does it).
- ▶ The functions reference each other via **calls**; a function call implies an active, *transient* use.
- ▶ **Values** are stored in **variables**, on which computation is performed by functions.

Verilog

- ▶ A **model** is described using static **module definitions**.
- ▶ Each **module** has an interface (i.e., what it does and how it can be used) and a body (i.e., how it does it).
- ▶ The modules reference each other via **instantiations**; a module instantiation implies an active, *permanent* use.
- ▶ **Values** are carried by **nets**, on which computation is performed by modules.

but, beware:

- ▶ on one hand, the analogy is attractive if you have some C programming experience, *but*
- ▶ on the other hand, the analogy is unattractive (perhaps even *dangerous*) because it's *imperfect* in various ways.

Part 1: foundational concepts (4)

► Example:

```
module fa( output wire co,
            output wire s,
            input  wire ci,
            input  wire x,
            input  wire y );

    wire w0, w1, w2;

    xor t0( w0, x, y );
    and t1( w1, x, y );

    xor t2( s, w0, ci );
    and t3( w2, w0, ci );

    or t4( co, w1, w2 );

endmodule
```

Part 1: foundational concepts (5)

- ▶ **Example:** a model can be described in
 1. a high-level, behaviour-oriented style, or
 2. a low-level, implementation-oriented style, or
 3. a *hybrid* of the two

so, e.g.,

Option #1: switch-level Verilog

At the lowest-level, the model can be described using individual transistors. For example, the four transistor instances

```
pmos( t, VDD, b );  
pmos( a, t, c );  
nmos( a, VSS, c );  
nmos( a, VSS, b );
```

replicate the previous circuit for a MOSFET-based NOR gate, meaning they continuously drive the wire a with the the result of evaluating $\neg(b \vee c)$.

Part 1: foundational concepts (5)

► **Example:** a model can be described in

1. a high-level, behaviour-oriented style, or
2. a low-level, implementation-oriented style, or
3. a *hybrid* of the two

so, e.g.,

Option #2: gate-level Verilog

Forces the model to be described at a low-level, using only primitive logic gates (e.g., AND, OR, NOT). For example, the gate instantiation

```
nor t( a, b, c );
```

continuously drives the wire a with the result of evaluating $\neg(b \vee c)$.

Part 1: foundational concepts (5)

- ▶ **Example:** a model can be described in
 1. a high-level, behaviour-oriented style, or
 2. a low-level, implementation-oriented style, or
 3. a *hybrid* of the two

so, e.g.,

Option #3: Register Transfer Level (RTL) Verilog

Uses a syntax similar to C, but focuses on describing the model in terms of the data-flow between components rather than high-level statements. For example, the continuous assignment

```
assign a = ~( b | c )
```

continuously drives the wire a with the the result of evaluating $\neg(b \vee c)$.

Part 1: foundational concepts (5)

► **Example:** a model can be described in

1. a high-level, behaviour-oriented style, or
2. a low-level, implementation-oriented style, or
3. a *hybrid* of the two

so, e.g.,

Option #4: behavioural-level Verilog

Allows a high-level, C-style description of the model using assignments, loops and conditional statements. For example, the procedural assignment

$$a = \neg(b \mid c)$$

sets the register a equal to the result of evaluating $\neg(b \vee c)$.

Part 2: low-level modelling (1)

Wires and values

► Concept: wires (resp. wire vectors)

- are a form of **net** used to *communicate* values,
- e.g.,
 - `wire w` ⇒ an internal 1-bit wire `w`
 - `wire [3 : 0] x` ⇒ an internal 4-bit wire vector `x`
 - `input wire [3 : 0] y` ⇒ an input 4-bit wire vector `y`
 - `output wire [3 : 0] z` ⇒ an output 4-bit wire vector `y`

Part 2: low-level modelling (2)

Wires and values

► Concept: values

1. support the concept of 3-state logic, e.g.,

- $\emptyset \Rightarrow 0$ (i.e., logical **false**)
- $1 \Rightarrow 1$ (i.e., logical **true**)
- $X \Rightarrow$ unknown (i.e., neither 1 or 0)
- $Z \Rightarrow$ high impedance (i.e., disconnected)

2. can be written in binary, decimal, or hexadecimal, e.g.,

- $2'b10 \Rightarrow$ a 2-bit binary literal, with value $10_{(2)}$, $2_{(10)}$, or $2_{(16)}$
- $8'd17 \Rightarrow$ a 8-bit decimal literal, with value $00010001_{(2)}$, $17_{(10)}$, or $11_{(16)}$
- $4'hF \Rightarrow$ a 4-bit hexadecimal literal, with value $1111_{(2)}$, $15_{(10)}$, or $F_{(16)}$

3. can include 3-state values on a per-bit basis, e.g.,

- $1'bX \Rightarrow$ a 1-bit binary literal; the bit is unknown
- $4'b10XZ \Rightarrow$ a 4-bit binary literal; the bits are high impedance, unknown, 0, and 1

Part 2: low-level modelling (3)

Wires and values

► Analogy:

C

- ▶ The definition

`char u ~> 8 separate 1-bit elements`

but `u` is typically used as 1 *single* 8-bit object.

- ▶ The definition

`char v[32] ~> 32 separate 8-bit elements`

and `v` is typically used as 32 *separate* 8-bit elements.

Verilog

- ▶ The definition

`wire x ~> 1 single 1-bit wire`

and `x` is used as 1 *single* 1-bit object.

- ▶ The definition

`wire [3 : 0] y ~> 4 separate 1-bit wires`

such that

1. `y` can be used as 1 *single* 4-bit object, or
2. `y` can be used as 4 *separate* 1-bit wires.

but, beware:

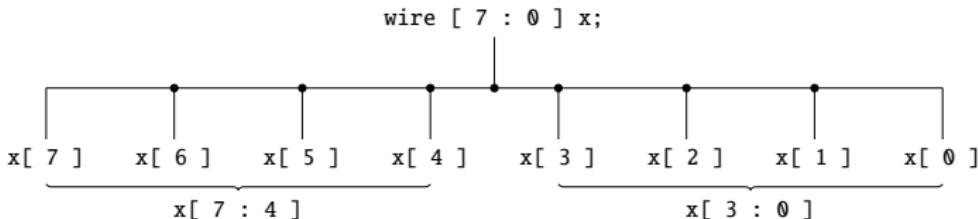

- ▶ a wire (resp. wire vector) cannot retain state (e.g., doesn't behave like a C variable),
- ▶ we need to *drive* a value on it.

Part 2: low-level modelling (4)

Wires and values

► Concept: subscript operator.

- consider a case where $x = 8'b11110000$, and

- we have that

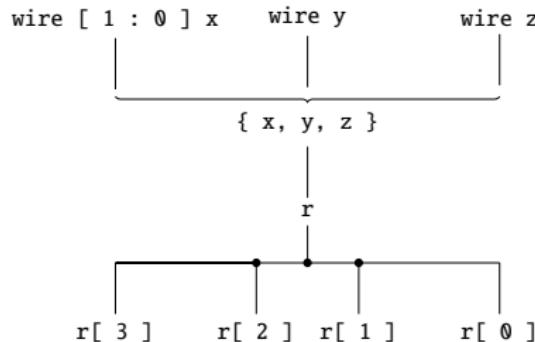

- $x[7], x[6], x[5]$ and $x[4]$ are all 1-bit wires with value $1'b1$,
- $x[3], x[2], x[1]$ and $x[0]$, are all 1-bit wires with value $1'b0$,
- $x[7 : 4]$ is a 4-bit wire vector with value $4'b1111$, and
- $x[3 : 0]$ is a 4-bit wire vector with value $4'b0000$.

Part 2: low-level modelling (5)

Wires and values

► Concept: concatenate operator.

- consider a case where $x = 2'b10$, $y = 1'b1$, and $z = 1'b0$, and

- we have that

- $\{ x, y, z \}$ is a 4-bit wire vector with value $4'b1010$,
- $r[3]$ is a 1-bit wire with value $1'b1$ (matching $x[1]$),
- $r[2]$ is a 1-bit wire with value $1'b0$ (matching $x[0]$),
- $r[1]$ is a 1-bit wire with value $1'b1$ (matching y), and
- $r[0]$ is a 1-bit wire with value $1'b0$ (matching z).

Part 2: low-level modelling (7)

Modules

► Concept: module definition

- are a passive (or static) *description* of a component,
- e.g.,

Listing (Verilog)

```
1 module mux2_1bit( output wire r,
2                     input  wire c,
3                     input  wire x,
4                     input  wire y );
5
6   ...
7
8 endmodule
```

Listing (Verilog)

```
1 module mux2_1bit( r, c, x, y );
2
3   output wire r;
4   input  wire c;
5   input  wire x;
6   input  wire y;
7
8   ...
9
10 endmodule
```

noting the two forms are equivalent.

Part 2: low-level modelling (8)

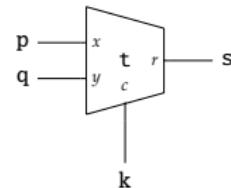

Modules

► Concept: module instantiation

- are an active (or dynamic) *use* of a component,
- e.g.,

```
mux2_1bit t( s, k, p, q );
```

↔

where we've

- created an instance of the `mux2_1bit` module identified by `t`, and
- connected the internal ports `r`, `c`, `x` and `y` to the external wires `s`, `k`, `p` and `q`

Part 2: low-level modelling (9)

Modules

► Analogy:

C

- ▶ A caller function invokes (or calls) a callee function.
- ▶ 1 *shared* copy of a callee function is used by n invocations.
- ▶ Each invocation executes in *sequence*, and *discontinuously*.

Verilog

- ▶ A instanciator module instantiates a instantatee module.
- ▶ n *separate* copies of a instantatee module are produced by n instantiations.
- ▶ Each instance operates in *parallel*, and *continuously*.

► **Concept: gate-level module implementation**

- describes module behaviour via
 - primitive (or built-in) modules, and/or
 - other user-defined modules,
- e.g.,

buf t0(r, x);	↔	$r = x$
not t1(r, x);	↔	$r = \neg x$
nand t2(r, x, y);	↔	$r = x \barwedge y$
nor t3(r, x, y);	↔	$r = x \barvee y$
and t4(r, x, y);	↔	$r = x \wedge y$
or t5(r, x, y);	↔	$r = x \vee y$
xor t6(r, x, y);	↔	$r = x \oplus y$

noting that multi-input variants such as

xor t8(r, w, x, y);	↔	$r = w \oplus x \oplus y$
xor t9(r, w, x, y, z);	↔	$r = w \oplus x \oplus y \oplus z$

are automatically available.

Part 2: low-level modelling (11)

Module implementation using gate-level Verilog

► Concept: User-Defined Primitives (UDPs)

- ▶ describe module behaviour via a truth table,
- ▶ doing so assumes it models a Boolean function of the form

$$f : \{0,1\}^n \rightarrow \{0,1\}$$

- ▶ e.g.,

Listing (Verilog)

```
1 primitive mux2_1bit( output r,
2                      input c,
3                      input x,
4                      input y );
5   table
6     0 0 ? : 0;
7     0 1 ? : 1;
8     1 ? 0 : 0;
9     1 ? 1 : 1;
10  endtable
11
12 endprimitive
```

Truth table

c	x	y	r
0	0	?	0
0	1	?	1
1	?	0	0
1	?	1	1

which can then be used per a user-defined module.

Part 2: low-level modelling (12)

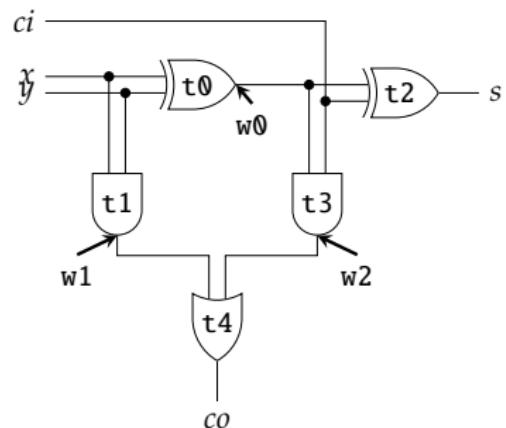

Module implementation using gate-level Verilog

► Example:

Listing (Verilog)

```
1 module fa( output wire co,
2             output wire s,
3             input  wire ci,
4             input  wire x,
5             input  wire y );
6
7   wire w0, w1, w2;
8
9   xor t0( w0, x, y );
10  and t1( w1, x, y );
11
12  xor t2( s, w0, ci );
13  and t3( w2, w0, ci );
14
15  or t4( co, w1, w2 );
16
17 endmodule
```

Circuit (full-adder)

Part 2: low-level modelling (13)

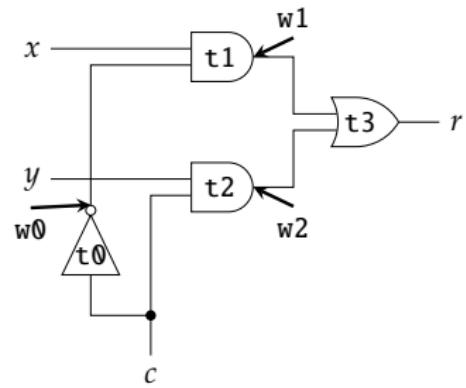

Module implementation using gate-level Verilog

► Example:

Listing (Verilog)

```
1 module mux2_1bit( output wire r,
2                     input  wire c,
3                     input  wire x,
4                     input  wire y );
5
6   wire w0, w1, w2;
7
8   not t0( w0, c );
9
10  and t1( w1, x, w0 );
11  and t2( w2, y, c );
12
13  or  t3( r, w1, w2 );
14
15 endmodule
```

Circuit (2-input, 1-bit multiplexer)

Part 2: low-level modelling (14)

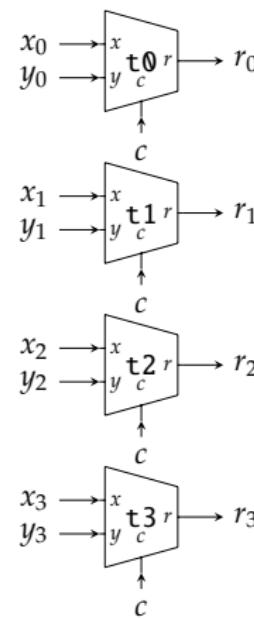

Module implementation using gate-level Verilog

► Example:

Listing (Verilog)

```
1 module mux2_4bit( output wire [ 3 : 0 ] r,
2                     input  wire           c,
3                     input  wire [ 3 : 0 ] x,
4                     input  wire [ 3 : 0 ] y );
5
6   mux2_1bit t0( r[ 0 ], c, x[ 0 ], y[ 0 ] );
7   mux2_1bit t1( r[ 1 ], c, x[ 1 ], y[ 1 ] );
8   mux2_1bit t2( r[ 2 ], c, x[ 2 ], y[ 2 ] );
9   mux2_1bit t3( r[ 3 ], c, x[ 3 ], y[ 3 ] );
10
11 endmodule
```

Circuit (2-input, 4-bit multiplexer)

Part 2: low-level modelling (15)

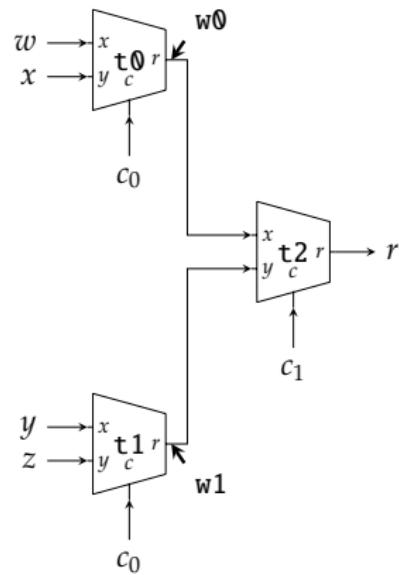

Module implementation using gate-level Verilog

► Example:

Listing (Verilog)

```
1 module mux4_1bit( output wire r,
2                     input wire c0,
3                     input wire c1,
4                     input wire w,
5                     input wire x,
6                     input wire y,
7                     input wire z );
8
9   wire w0, w1;
10
11  mux2_1bit t0( w0, c0, w, x );
12  mux2_1bit t1( w1, c0, y, z );
13  mux2_1bit t2( r, c1, w0, w1 );
14
15 endmodule
```

Circuit (4-input, 1-bit multiplexer)

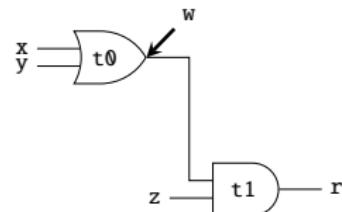

Part 2: low-level modelling (16)

Module implementation using RTL-level Verilog

► Concept: Register Transfer Level (RTL) module implementation

- describes module behaviour via
 1. a set of **continuous assignments**, plus
 2. any additional gate-level description
- e.g.,

assign r = (x | y) & z; \mapsto or t0(w, x, y);
 and t1(r, w, z); \mapsto

- the LHS *must* be a wire or wire vector, whereas
 - the RHS can contain many C-style operators
 - **arithmetic operators**, e.g., +, -, and *,
 - **logical operators**, e.g., <<, >>, ~, &, |, and ^,
 - **comparison operators**, e.g., ==, >, and <.
- involving wires or wire vectors as operands.

but, beware:

- it's tempting to think of this as analogous to a C assignment,
- this is dangerous, because the RTL version is *continuous*.

► **Concept: reduction operator.**

- consider a case where wire [3 : 0] x, wire [3 : 0] y, and wire c,
 - we have that

$$\wedge x \mapsto ((x[3] \wedge x[2]) \wedge x[1]) \wedge x[0]$$

so is analogous to `reduce` (or `foldr`) in Haskell.

► **Concept: ternary operator.**

- consider a case where `wire [3 : 0] x`, `wire [3 : 0] y`, and `wire c`,
- we have that

$$c ? y : x \mapsto \begin{cases} x & \text{if } c = 0 \\ y & \text{if } c = 1 \end{cases}$$

so is analagous to a 2-input multiplexer.

Part 2: low-level modelling (19)

Module implementation using RTL-level Verilog

► Example:

Listing (Verilog)

```
1 module fa( output wire co,
2             output wire s,
3             input  wire ci,
4             input  wire x,
5             input  wire y );
6
7   wire w0, w1, w2;
8
9   xor t0( w0,  x,  y );
10  and t1( w1,  x,  y );
11
12  xor t2( s, w0, ci );
13  and t3( w2, w0, ci );
14
15  or t4( co, w1, w2 );
16
17 endmodule
```

Listing (Verilog)

```
1 module fa( output wire co,
2             output wire s,
3             input  wire ci,
4             input  wire x,
5             input  wire y );
6
7   wire [ 1 : 0 ] t;
8
9   assign t  = ci + x + y;
10
11  assign s  = t[ 0 ];
12  assign co = t[ 1 ];
13
14 endmodule
```

Part 2: low-level modelling (19)

Module implementation using RTL-level Verilog

► Example:

Listing (Verilog)

```
1 module fa( output wire co,
2             output wire s,
3             input  wire ci,
4             input  wire x,
5             input  wire y );
6
7   wire w0, w1, w2;
8
9   xor t0( w0,  x,  y );
10  and t1( w1,  x,  y );
11
12  xor t2( s, w0, ci );
13  and t3( w2, w0, ci );
14
15  or t4( co, w1, w2 );
16
17 endmodule
```

Listing (Verilog)

```
1 module fa( output wire co,
2             output wire s,
3             input  wire ci,
4             input  wire x,
5             input  wire y );
6
7   assign { co, s } = ci + x + y;
8
9 endmodule
```

Part 2: low-level modelling (20)

Module implementation using RTL-level Verilog

► Example:

Listing (Verilog)

```
1 module mux2_1bit( output wire r,
2                     input  wire c,
3                     input  wire x,
4                     input  wire y );
5
6   wire w0, w1, w2;
7
8   not t0( w0,  c );
9
10  and t1( w1,  x, w0 );
11  and t2( w2,  y, c );
12
13  or  t3( r,   w1, w2 );
14
15 endmodule
```

Listing (Verilog)

```
1 module mux2_1bit( output wire r,
2                     input  wire c,
3                     input  wire x,
4                     input  wire y );
5
6   assign r = c ? y : x;
7
8 endmodule
```

Part 2: low-level modelling (21)

Module implementation using RTL-level Verilog

► Example:

Listing (Verilog)

```
1 module mux2_4bit( output wire [ 3 : 0 ] r,
2                     input  wire      c,
3                     input  wire [ 3 : 0 ] x,
4                     input  wire [ 3 : 0 ] y );
5
6   mux2_1bit t0( r[ 0 ], c, x[ 0 ], y[ 0 ] );
7   mux2_1bit t1( r[ 1 ], c, x[ 1 ], y[ 1 ] );
8   mux2_1bit t2( r[ 2 ], c, x[ 2 ], y[ 2 ] );
9   mux2_1bit t3( r[ 3 ], c, x[ 3 ], y[ 3 ] );
10
11 endmodule
```

Listing (Verilog)

```
1 module mux2_4bit( output wire [ 3 : 0 ] r,
2                     input  wire      c,
3                     input  wire [ 3 : 0 ] x,
4                     input  wire [ 3 : 0 ] y );
5
6   assign r = c ? y : x;
7
8 endmodule
```

Part 2: low-level modelling (22)

Module implementation using RTL-level Verilog

► Example:

Listing (Verilog)

```
1 module mux4_1bit( output wire r,
2                     input wire c0,
3                     input wire c1,
4                     input wire w,
5                     input wire x,
6                     input wire y,
7                     input wire z);
8
9   wire w0, w1, w2, w3, w4, w5;
10
11  not t0( w0, c0 );
12  not t1( w1, c1 );
13
14  and t2( w2, w0, w1, w );
15  and t3( w3, c0, w1, x );
16  and t4( w4, w0, c1, y );
17  and t5( w5, c0, c1, z );
18
19  or  t6( r, w2, w3, w4, w5 );
20
21 endmodule
```

Listing (Verilog)

```
1 module mux4_1bit( output wire r,
2                     input wire c0,
3                     input wire c1,
4                     input wire w,
5                     input wire x,
6                     input wire y,
7                     input wire z );
8
9   assign r = c1 ? ( c0 ? z : y ) :
10                  ( c0 ? x : w ) ;
11
12 endmodule
```

Part 3: high-level modelling (1)

Registers

► Concept: registers (resp. register vectors)

- are a form of **net** used to *store* values (i.e., retain state),
- e.g.,
 - `reg w` \Rightarrow an internal 1-bit register `w`
 - `reg [3 : 0] x` \Rightarrow an internal 4-bit register vector `x`

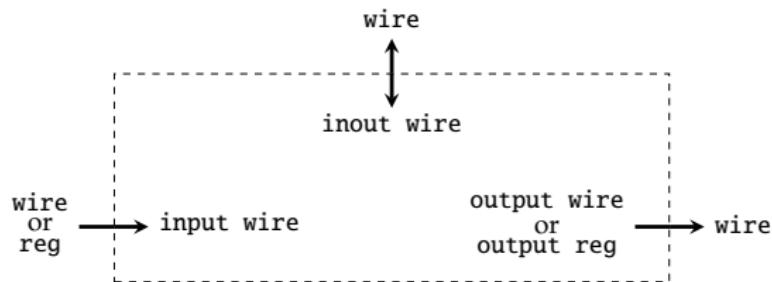

but, beware: registers *feel* analogous to C-style variables, but care is required re. use.

Part 3: high-level modelling (2)

Registers

► Concept: module interfacing rules

Definition

which are *somewhat* intuitive when read as

input port : { externally can be a wire or reg
internally must be a wire

output port : { internally can be a wire or reg
externally must be a wire

i.e., we must be pessimistic when crossing the module boundary.

Part 3: high-level modelling (3)

Module implementation using behavioural-level Verilog

► Concept: behavioural-level module implementation

- describes module behaviour via
 - (at least partly) using **processes**,
 - each process is formed from **blocks of statements**,
 - each process is “executed” in parallel with the others once **triggered**.
- e.g.,

Listing (Verilog)

```
1 initial begin:id  
2 ...  
3 end
```

Listing (Verilog)

```
1 always begin:id  
2 ...  
3 end
```

shows the two process types

- **initial** ⇒ triggered only *once* (when the module is first powered-on)
- **always** ⇒ triggered in a *loop* (as long as the module is powered-on)

noting the right-hand case is problematic as is ...

Part 3: high-level modelling (3)

Module implementation using behavioural-level Verilog

► Concept: behavioural-level module implementation

- describes module behaviour via
 - (at least partly) using **processes**,
 - each process is formed from **blocks of statements**,
 - each process is “executed” in parallel with the others once **triggered**.
- e.g.,

Listing (Verilog)

```
1 always @ ( x ) begin  
2   ...  
3 end
```

Listing (Verilog)

```
1 always @ ( posedge x ) begin  
2   ...  
3 end
```

Listing (Verilog)

```
1 always @ ( negedge x ) begin  
2   ...  
3 end
```

shows processes that are triggered via a **sensitivity list**:

- `@(x)` ⇒ triggers when `x` changes
- `@(posedge x)` ⇒ triggers when `x` changes from 0 to 1 (a positive edge)
- `@(negedge x)` ⇒ triggers when `x` changes from 1 to 0 (a negative edge)

Part 3: high-level modelling (4)

Module implementation using behavioural-level Verilog

- ▶ **Concept:** procedural assignment, e.g.,

Listing (Verilog)

```
1 module foo( input wire clk );
2
3   reg x, y;
4
5   always @ ( posedge clk ) begin
6     x = 1'b0;
7     y = 1'b1;
8   end
9
10 endmodule
```

which differ from a continuous assignment: they

1. must use a register as the LHS (versus a wire), and
2. the LHS is assigned to whatever the RHS evaluates to when the statement executes (versus whenever the RHS changes).

Part 3: high-level modelling (4)

Module implementation using behavioural-level Verilog

- ▶ **Concept:** procedural assignment, e.g.,

Listing (Verilog)

```
1 module foo( input wire clk );
2
3   reg x, y;
4
5   always @ ( posedge clk ) begin
6     x = 1'b0;
7     y = 1'b1;
8   end
9
10 endmodule
```

which can introduce modelled **delay**:

- ▶ a **regular** delay, e.g.,

```
#10 x = 0;
```

means that, relative to the previous statement, this one will execute 10 time units later, whereas

- ▶ an **intra-assignment** delay, e.g.,

```
x = #10 0;
```

means that the RHS is evaluated straight away, but only assigned to the LHS after 10 time units.

Part 3: high-level modelling (4)

Module implementation using behavioural-level Verilog

- ▶ **Concept:** procedural assignment, e.g.,

Listing (Verilog)

```
1 module foo( input wire clk );
2
3   reg x, y;
4
5   always @ ( posedge clk ) begin
6     x = 1'b0;
7     y = 1'b1;
8   end
9
10 endmodule
```

which come in **blocking** or **non-blocking** variants:

- ▶ if we write

```
x = 0; y = 1;
```

then the assignment to y is blocked until the assignment to x is executed, whereas

- ▶ if we write

```
x <= 0; y <= 1;
```

then the assignments to x and y are executed in parallel.

Part 3: high-level modelling (5)

Module implementation using behavioural-level Verilog

- ▶ Concept: conditional statements, e.g.,

Listing (Verilog)

```
1 module bar( input wire clk );
2
3   reg x, y;
4
5   always @ ( posedge clk ) begin
6     if( x == 1'b0 ) begin
7       y = 1'b1;
8     end else begin
9       y = 1'b0;
10    end
11  end
12
13 endmodule
```

Listing (Verilog)

```
1 module baz( input wire clk );
2
3   reg x, y;
4
5   always @ ( posedge clk ) begin
6     case( x )
7       1'b0 : y = 1'b1;
8       1'b1 : y = 1'b0;
9     default : y = 1'b0;
10    endcase
11  end
12
13 endmodule
```

noting that

- ▶ it starts to be attractive to leave out the `begin` and `end` keywords for single line blocks; this is equivalent to the same rule with “curly braces” in C,
- ▶ we need to take care with unknown or high impedance values; if `x` doesn’t equal 0 or 1 you may get unexpected behaviour.

Part 3: high-level modelling (6)

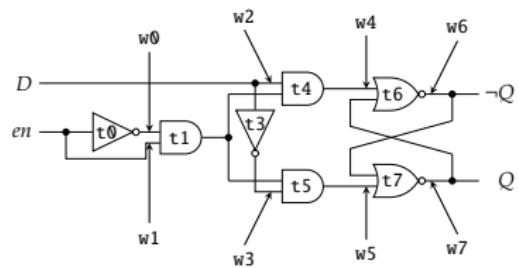

Module implementation using behavioural-level Verilog

► Example:

Listing (Verilog)

```
1 module dff( input  wire  en,
2               input  wire   D,
3               output wire   Q );
4
5   wire w0, w1, w2, w3, w4, w5, w6, w7;
6
7   not t0( w0,      en );
8   and t1( w1, w0,  en );
9
10  buf t2( w2, D      );
11  not t3( w3, D      );
12
13  and t4( w4, w2, w1 );
14  and t5( w5, w3, w1 );
15
16  nor t6( w6, w4, w7 );
17  nor t7( w7, w5, w6 );
18
19  buf t8( Q, w7      );
20
21 endmodule
```

Circuit

Part 3: high-level modelling (6)

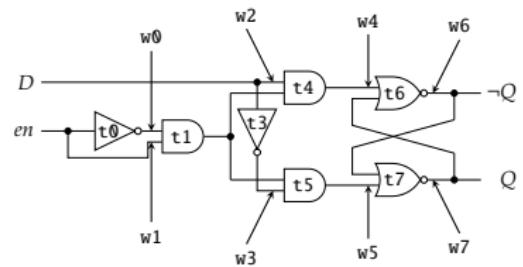

Module implementation using behavioural-level Verilog

► Example:

Listing (Verilog)

```
1 module dff( input  wire  en,
2               input  wire  D,
3               output wire  Q );
4
5   reg t;
6
7   assign Q = t;
8
9   always @ ( posedge en ) begin
10     t = D;
11   end
12
13
14 endmodule
```

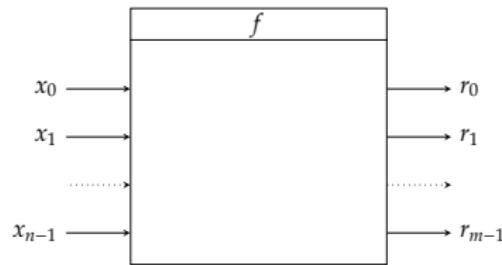

Circuit

Part 4: development concepts (1)

Testing

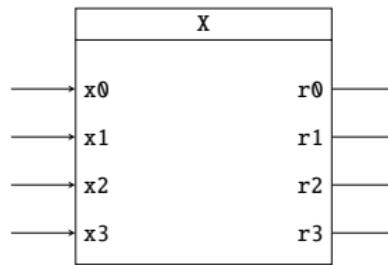

- **Concept:** test stimulus (or test harness).

Part 4: development concepts (1)

Testing

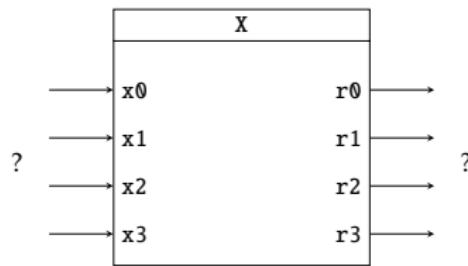

- ▶ **Concept:** test stimulus (or test harness).

Part 4: development concepts (1)

Testing

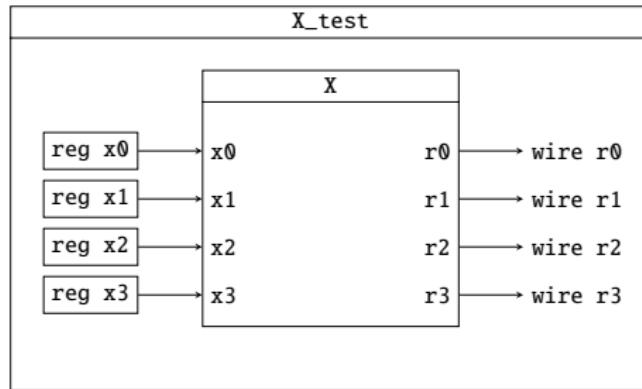

- **Concept:** test stimulus (or test harness).

Part 4: development concepts (1)

Testing

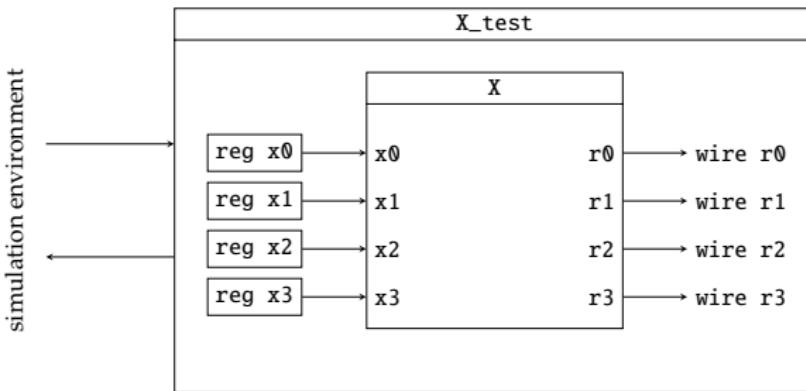

- ▶ **Concept:** test stimulus (or test harness).

Part 4: development concepts (1)

Testing

- ▶ **Concept:** test stimulus (or test harness)

noting that `X_test`

- ▶ is termed a (or the) **top-level module** in the sense it has no inputs or outputs,
- ▶ can interact with the simulation environment via **system tasks** and **system functions**, e.g.,
 - `$random` ⇒ generates random value(s)
 - `$display` ⇒ displays value(s) synchronously
 - `$monitor` ⇒ displays value(s) asynchronously
 - `$stop` ⇒ halt current simulation
 - `$finish` ⇒ terminate current simulation
- ▶ will apply some form of **test strategy** to the instance of `X`.

Part 4: development concepts (2)

Testing

► Example:

Listing (Verilog)

```
1 module fa_test();
2
3   wire t_co,      t_s;
4   reg  t_ci; t_x, t_y;
5
6   fa t( .co( t_co ), .s( t_s ), .ci( t_ci ), .x( t_x ), .y( t_y ) );
7
8   initial begin
9     #10 t_ci = 1'b0; t_x = 1'b0; t_y = 1'b0;
10    $display( "co=%b s=%b ci=%b x=%b y=%b", t_co, t_s, t_ci, t_x, t_y );
11    #10 t_ci = 1'b0; t_x = 1'b0; t_y = 1'b1;
12    #10 $display( "co=%b s=%b ci=%b x=%b y=%b", t_co, t_s, t_ci, t_x, t_y );
13    #10 t_ci = 1'b0; t_x = 1'b1; t_y = 1'b0;
14    #10 $display( "co=%b s=%b ci=%b x=%b y=%b", t_co, t_s, t_ci, t_x, t_y );
15    #10 t_ci = 1'b0; t_x = 1'b1; t_y = 1'b1;
16    #10 $display( "co=%b s=%b ci=%b x=%b y=%b", t_co, t_s, t_ci, t_x, t_y );
17
18   #10 $finish;
19 end
20
21 endmodule
```

Part 4: development concepts (3)

Testing

► Example:

Listing (Verilog)

```
1 module fa_test();
2
3   wire t_co,      t_s;
4   reg  t_ci; t_x, t_y;
5
6   fa t( .co( t_co ), .s( t_s ), .ci( t_ci ), .x( t_x ), .y( t_y ) );
7
8   initial begin
9     $monitor( "co=%b s=%b ci=%b x=%b y=%b", t_co, t_s, t_ci, t_x, t_y );
10
11    $monitoron;
12
13    #10 t_ci = 1'b0; t_x = 1'b0; t_y = 1'b0;
14    #10 t_ci = 1'b0; t_x = 1'b0; t_y = 1'b1;
15    #10 t_ci = 1'b0; t_x = 1'b1; t_y = 1'b0;
16    #10 t_ci = 1'b0; t_x = 1'b1; t_y = 1'b1;
17
18    #10 $monitoroff;
19    $finish;
20  end
21
22 endmodule
```

Part 4: development concepts (4)

"Quality-of-life" features

- **Concept:** a “better” model \leadsto greater **generalisation, maintainability**, etc.

1. We can use a **pre-processor** to

- ▶ define symbolic names for literals, e.g.,

```
`define TRUE 1
```

then

- ▶ use those symbolic names e.g.,

```
assign r = x ^ `TRUE;
```

2. We can use **named ports** to avoid misconnections, e.g.,

```
fa t( .co(a), .s(b), .ci(c), .x(d), .y(e) );
```

is the same as

```
fa t( .co(a), .s(b), .ci(c), .y(e), .x(d) );
```

3. We can **parametrise** modules:

- ▶ their interface and behaviour is specified by a *single* fragment of source code,
- ▶ each instance can be altered to suit the context it is used in.

4. We can **generate** “regular” fragments of source code (cf. meta-programming, versus “copy and paste”).

Conclusions

► Take away points:

1. In essence, a HDL model is just machine-readable short-hand for a design you could develop and reason about on paper.
2. It's important to remember that, despite appearances,

HDL modelling \neq software development,

i.e., you *still* have to understand the fundamentals and “think in hardware”.

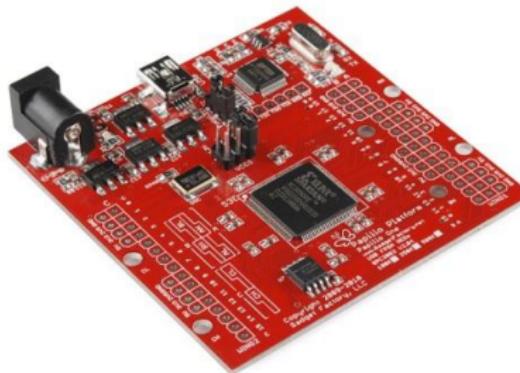

3. Even within this unit, HDLs offer various useful properties, e.g.,

- ▶ adopt a more accurate experimental approach to design,
- ▶ deal with designs of a larger scale,
- ▶ interface with other concepts (e.g., verification),
- ▶ ...

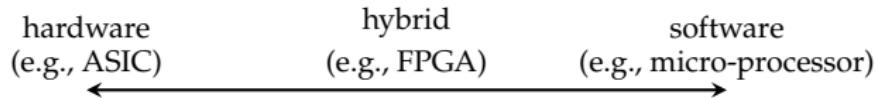

so some up-front, invested effort *could* pay off ...

Conclusions

- ▶ Example: Field Programmable Gate Arrays (FPGAs).

- ▶ basic idea is that the hardware fabric is reconfigurable, so, in a sense,

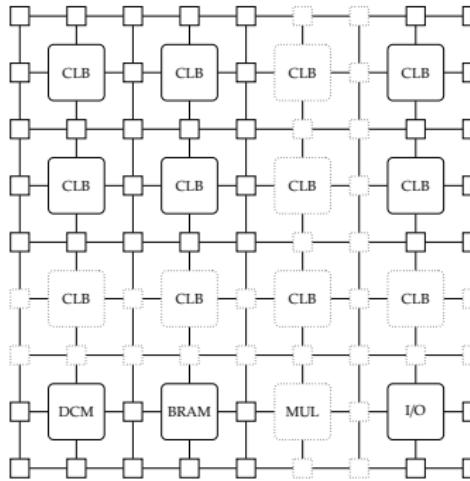

- and therefore offers a trade-off:

efficiency \simeq hardware
flexibility \simeq software

Conclusions

- ▶ Example: Field Programmable Gate Arrays (FPGAs).

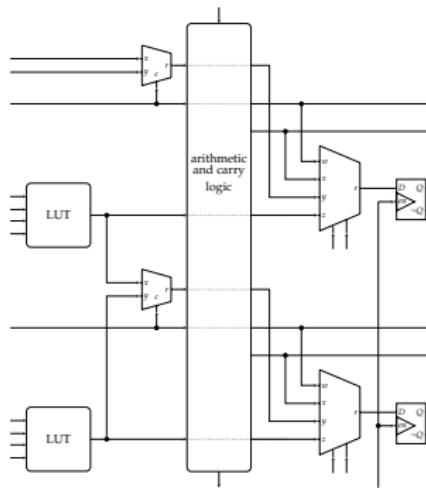

- ▶ basic idea is that the hardware fabric is reconfigurable, so, in a sense,

- ▶ and therefore offers a trade-off:

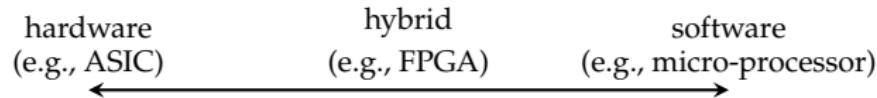

efficiency \simeq hardware
flexibility \simeq software

Conclusions

- ▶ Example: Field Programmable Gate Arrays (FPGAs).

- ▶ basic idea is that the hardware fabric is reconfigurable, so, in a sense,

- ▶ and therefore offers a trade-off:

$$\begin{array}{ccc} \text{efficiency} & \simeq & \text{hardware} \\ \text{flexibility} & \simeq & \text{software} \end{array}$$
